

ABSTRACT

A system and method is presented for the restricting features in a wireless network. A database contains representations of rules that restrict the features of terminals connected to a base station. For an incoming communication, a determination is made as to which terminal is associated with the call, and a database is accessed to look up rules governing restrictions on the terminal and/or the base station connected to the terminal; the terminal is then activated depending on the restrictions. For outgoing communication, when a signal associated with a request for an outgoing communication is received from a terminal, a database is accessed to look up rules governing restrictions; the terminal is connected for outgoing communication depending on whether the restrictions allow it.
